PFIESTERIA

Pfiesteria is a recently recognized organism first identified in 1991 in North Carolina and this summer in the Chesapeake Bay of Maryland and Virginia. It gained widespread publicity because of large fish kills and many fish developing open sores. It is a very complex organism that can behave both like a plant and an animal. It is a dinoflagellate similar to the marine organism that causes "Red Tide". Under most conditions, it is innocuous. However, under conditions of high temperature, low dissolved oxygen and high nutrient loading, it produces a powerful toxin.

Human health complaints have occurred as a result of skin contact or inhalation of the toxin. This toxin is not contagious or infectious, and cannot be "caught" like a cold. Well-documented human health effects linked to Pfiesteria have occurred in laboratory conditions, where researchers were working with the organism in close proximity and in high concentrations.

Consistent complaints include memory loss, confusion and/or acute skin burning (on direct contact with water). Other frequent complaints are headache, skin rash, eye irritation, upper respiratory system irritation, muscle cramps and gastrointestinal tract irritation (nausea, vomiting, diarrhea and/or abdominal cramps).

Although there appears to be a causal relationship between Pfiesteria exposure in marine waters and health complaints, this relationship has not yet been verified. Never the less, given the concern raised by these reported health effects, we need to be prudent when potentially exposed to Pfiesteria toxin.

Do not to handle fish with lesions unless you have to. If it is necessary, wear impermeable gloves.

Avoid swimming or skiing in an area where a fish kill is occurring and/or fish with open lesions are being reported.

Because of the uncertainty of consumer health risks, you should take normal precautions and use common sense: never eat fish that exhibit evidence of sores or disease. Do not eat fish that seem diseased or dying when caught.

Consumers should completely cook fish and crabs. Normal precautions should be taken when eating raw shellfish.
